Project Name	Automated Network Request Management
Team ID	
Maximum Marks	

Journey Map: Network Access Request

Scenario: A Security Operations (SecOps) alert flags an infected server, and a Network Administrator must immediately isolate the compromised asset by shutting down its firewall ports using ServiceNow's automated pipelines.

Journey Phase	User Actions & Goals	Experience & Opportunities
1. Entice (Awareness)	Action: Receives a critical security alert showing lateral movement from a specific server IP. Touchpoints: SIEM dashboard, high-priority PagerDuty/SMS alert. Goal: "Help me isolate this asset immediately before the breach spreads."	[+] Glad that an automated emergency pathway exists in ServiceNow. [-] High anxiety and adrenaline due to the active security risk. Idea: Integrate the SIEM directly with ServiceNow so a draft isolation ticket is auto-created with the IP data already filled in.

2. Enter <i>(Beginning)</i>	Action: Logs into ServiceNow and bypasses the standard catalog to open the "Emergency Network Control" workspace. Touchpoints: Admin console, Emergency Dashboard. Goal: "Help me bypass standard multi-day change boards for this crisis."	[+] The interface clearly separates emergency overrides from standard changes. [-] Minor confusion if emergency validation options require too many clicks. Idea: Implement a single-click "Quarantine Asset" button on the primary network admin dashboard for verified security incidents.
3. Engage <i>(Core Process)</i>	Action: Enters the infected target IP, selects "Total Network Isolation," and overrides standard CAB approvals with an emergency justification token. Touchpoints: Validated intake form, secure credential override block. Goal: "Help me execute this securely without human error while under pressure."	[+] System instantly auto-verifies the IP location and locks out conflicting options to prevent accidental wide-scale outages. [-] Typing errors could isolate the wrong subnet if input isn't locked down. Idea: Use an automated drop-down menu populated directly from active CMDB live assets instead of allowing any manual IP typing.

4. Exit <i>(Finishing)</i>	Action: Submits the form; ServiceNow Integration Hub immediately executes API scripts on the core firewalls to block all traffic to the IP. Touchpoints: Execution logs, real-time progress wheel. Goal: "Confirm for me right now that the port is completely closed."	[+] Zero human delay; the API block completes in under 30 seconds instead of hours. [-] Severe stress if the API integration times out or throws an unhandled error code. Idea: Implement an instant automated ping-test directly within the ticket to verify that the target IP is officially unreachable on the network.
5. Extend <i>(Aftermath)</i>	Action: Reviews the final, automatically generated audit trail showing the approval token, API logs, and updated CMDB record status. Touchpoints: ServiceNow post-incident report, SecOps handoff log. Goal: "Ensure my compliance records are bulletproof for the post-mortem review."	[+] The immutable log satisfies auditors without requiring hours of manual documentation afterward. [-] Forgetting to reverse the block once the server is cleaned if a reminder isn't set. Idea: Automatically schedule a standard "Review Isolation Status" ticket 48 hours later to remind the team to safely remediate and restore access.
